

Code Review and Quality: Using AI to Improve Code Quality and Readability

2303A51836

Lab-10.3

Problem Statement 1: AI-Assisted Bug Detection

Given Code

```
def factorial(n):  
    result = 1  
    for i in range(1, n):  
        result = result * i  
    return result
```

Testing

```
print(factorial(5))
```

Output:

24

Issue Identified

The function contains an **off-by-one error**.

The loop range(1, n) stops at n-1, so it does not multiply by n.

Corrected Code

```
def factorial(n):
```

```
if n < 0:  
    raise ValueError("Factorial is not defined for negative numbers")  
  
if n == 0:  
    return 1  
  
  
result = 1  
  
for i in range(1, n + 1):  
    result *= i  
  
return result
```

Correct Output:

120

Comparison

Manual Fix

Fixed range to n+1

No edge case handling

AI improved robustness by handling edge cases.

AI Fix

Fixed range and added validation

Problem Statement 2: Improving Readability & Documentation

Original Code

```
def calc(a, b, c):  
    if c == "add":  
        return a + b  
  
    elif c == "sub":
```

```
    return a - b

elif c == "mul":
    return a * b

elif c == "div":
    return a / b
```

Issues

- Poor function name (calc)
- No documentation
- No exception handling
- No input validation

Improved Code

```
def calculate(number1, number2, operation):
    if not isinstance(operation, str):
        raise TypeError("Operation must be a string")

    if operation == "add":
        return number1 + number2

    elif operation == "sub":
        return number1 - number2

    elif operation == "mul":
        return number1 * number2

    elif operation == "div":
        if number2 == 0:
            raise ZeroDivisionError("Cannot divide by zero")
        return number1 / number2
```

```
else:  
    raise ValueError("Invalid operation")
```

Problem Statement 3: Enforcing PEP8 Standards

Original Code

```
def Checkprime(n):  
    for i in range(2, n):  
        if n % i == 0:  
            return False  
    return True
```

PEP8 Violations

- Function name not in snake_case
- No input validation
- No docstring

Refactored Code

```
def check_prime(n):
```

```
    if n <= 1:  
        return False
```

```
    for i in range(2, n):  
        if n % i == 0:  
            return False  
    return True
```

Problem Statement 4: AI as a Code Reviewer

Original Code

```
def processData(d):  
    return [x * 2 for x in d if x % 2 == 0]
```

Issues

- Poor naming
- No validation
- No type hints
- No documentation

Improved Code

```
from typing import List, Union
```

```
def double_even_numbers(numbers: List[Union[int, float]]) -> List[Union[int, float]]:
```

```
    if not isinstance(numbers, list):  
        raise TypeError("Input must be a list")  
  
    return [  
        num * 2  
        for num in numbers  
        if isinstance(num, (int, float)) and num % 2 == 0  
    ]
```

Reflection

AI should act as an **assistant**, not a replacement for human reviewers.
It speeds up reviews but human judgment is still essential.

Problem Statement 5: AI-Assisted Performance Optimization

Original Code

```
def sum_of_squares(numbers):
    total = 0
    for num in numbers:
        total += num ** 2
    return total
```

Time Complexity

$O(n)$

Optimized Code

```
def sum_of_squares_optimized(numbers):
    return sum(x * x for x in numbers)
```

Comparison

Original	Optimized
Uses manual loop	Uses generator expression
Slightly longer	More concise
Same time complexity	
Cleaner implementation	

Original	Optimized
Uses manual loop	Uses generator expression
Slightly longer	More concise
Same time complexity	
Cleaner implementation	

Trade-off Discussion

- Optimized version improves readability.
- For very large datasets, NumPy can provide further speed improvements.
- Built-in functions are generally faster and more Pythonic.
